Summary

- PROBLEM:** Accurately predicting everyday end-user experience (UX) on laptops
GeekBench, SPEC etc. measure the "peak" performance of subsystems, but not the "average" system UX on everyday tasks.
- SCOPE:** Chromebook laptops, which mainly run web applications on ChromeOS
- 100K data points from 54 Chromebooks on 9 UX metrics from Chrome browser
- Regression models are trained to predict UX metric values from hardware specs

Methodology

- Train one regression model per UX metric to estimate that metric's value from a laptop's hardware specifications

Estimated Metric Value Regression Model Model Parameters

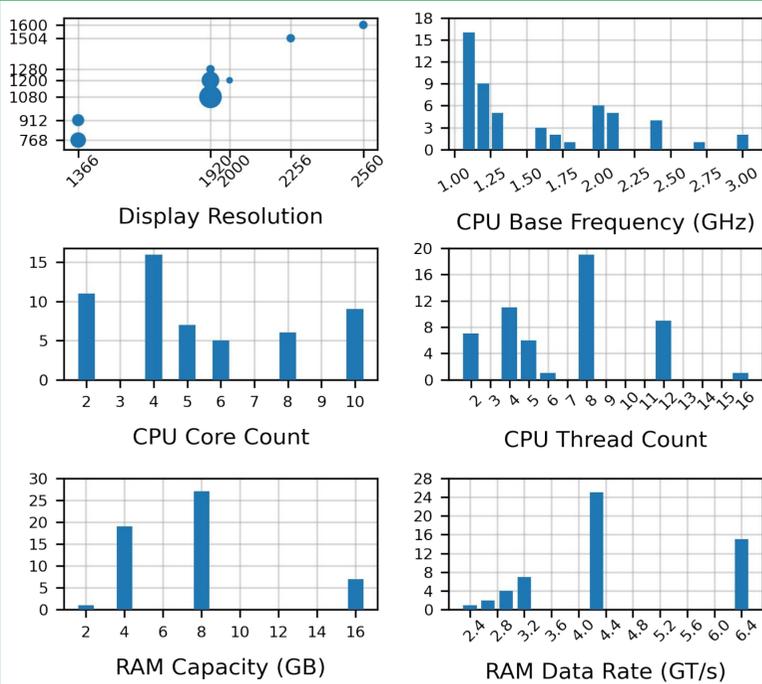

$$\hat{y}_m = f_m(\mathbf{x}, \hat{\beta})$$

where

$$\mathbf{x} = \langle x_{\text{cpu_freq}}, \dots, x_{\text{ram_capacity}}, \dots, x_{\text{display_res}} \rangle$$

- Gradient Boosted Regression Trees (GBRTs)
- Mean Squared Error (MSE) loss function
- Grid search to optimize hyperparameters

Data Collection

- Feature vector includes one-hot encoded System-on-Chip (SoC) vendor name
- Display resolution reduced to an integer: pixel count = horizontal × vertical pixels
- Automated tests for UX metric collection mimic typical end-user tasks, including web browsing, document editing, audio/video playback when Chromebooks are on AC power

UX Metrics

Latency

- Startup Time**
Time (ms) since app invocation to window launch
- Tab Switch Time**
Time (ms) since a tab switch event to the first rendered frame
- Largest Contentful Paint**
Time (ms) taken to paint the largest image or text block

Responsiveness

- Janky Intervals**
Number of 100ms intervals in which a user event was waiting in queue
- Key Press Delay**
Time (ms) taken by an app to start handling a key press event
- Mouse Press Delay**
Time (ms) taken by an app to start handling a mouse press event

Smoothness

- Dropped Frames**
Fraction (%) of frames dropped during scrolling or update
- Window Animation**
Relative (%) FPS (compared to 60) during window hiding animation
- Tab Switch Animation**
Relative (%) FPS (compared to 60) during tab switching animation

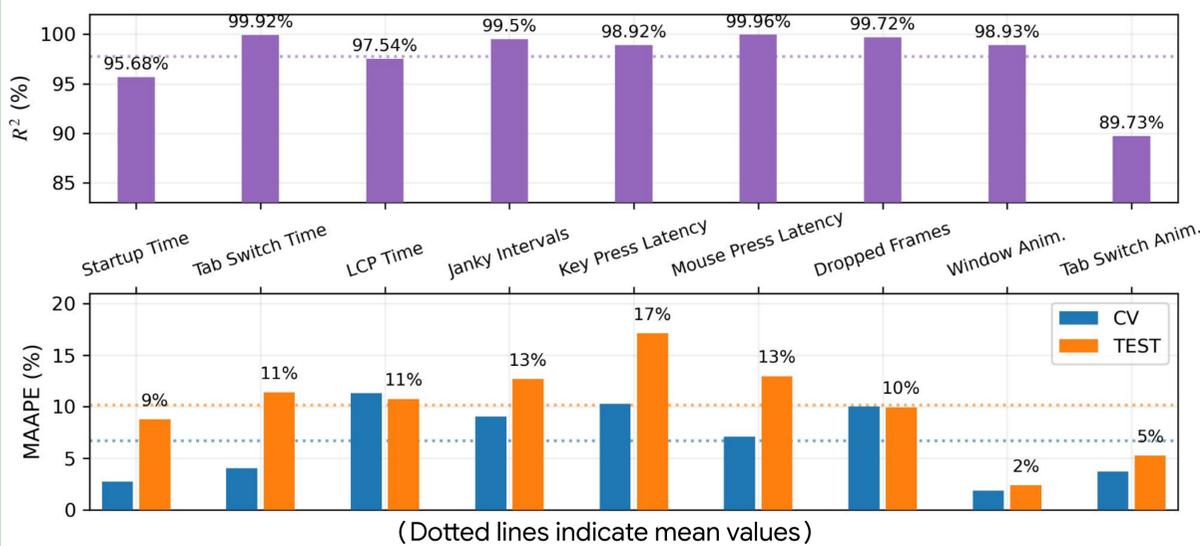

Key Findings

Kendall's Rank (τ) Correlation on Hardware Specs & UX Metrics:

| | Latency | | | Responsiveness | | | Smoothness | | |
|--------------------|---------|------|------|----------------|------|------|------------|-----|------|
| CPU Base Frequency | -0.1 | -0.2 | -0.3 | -0.1 | -0.1 | -0.2 | -0.1 | 0.1 | -0.1 |
| CPU Core Count | -0.2 | -0.3 | -0.2 | -0.2 | -0.3 | -0.3 | -0.3 | 0.2 | -0.2 |
| CPU Thread Count | -0.3 | -0.5 | -0.5 | -0.4 | -0.5 | -0.5 | -0.4 | 0.4 | 0 |
| RAM Capacity | -0.3 | -0.5 | -0.6 | -0.6 | -0.5 | -0.5 | -0.5 | 0.5 | 0.1 |
| RAM Data Rate | -0.4 | -0.4 | -0.3 | -0.3 | -0.5 | -0.4 | -0.3 | 0.3 | -0.2 |
| Display Resolution | -0.3 | -0.3 | -0.4 | -0.3 | -0.3 | -0.3 | -0.2 | 0.2 | -0.2 |

CPU thread count and RAM capacity show strongest correlation with better UX
 Latency and frame drop correlate **negatively** Animation smoothness correlate **positively**

R² fits and MAAPE errors of GBRT predictors:

High R² ⇒ Models capture data variance well ("in-sample": on training dataset)
Low MAAPE ⇒ Models predict accurately ("out-of-sample": on test & CV datasets)

MAAPE provides a stable relative error, even when the true values are zero

Normalized Permutation Feature Importance for GBRTs:

| | Latency | | | Responsiveness | | | Smoothness | | |
|--------------------|---------|-----|-----|----------------|-----|-----|------------|-----|-----|
| SoC Vendor | | 0.5 | 0.1 | 0.5 | 0.1 | 0.2 | 0.1 | | |
| CPU Base Frequency | 0.2 | 0.1 | 0.2 | 0.2 | 0.2 | 0.2 | 0.1 | 0.1 | 0.3 |
| CPU Core Count | 0.2 | | | | | | | 0.2 | 0.1 |
| CPU Thread Count | 0.1 | 0.2 | 0.6 | 0.2 | 0.5 | 0.4 | 0.2 | 0.2 | 0.1 |
| RAM Capacity | 0.1 | | | | | | 0.4 | 0.2 | |
| RAM Data Rate | 0.3 | 0.1 | 0.1 | 0.1 | 0.1 | 0.2 | 0.1 | 0.3 | 0.1 |
| Display Resolution | 0.1 | | | 0.1 | | | | | 0.3 |

(White cells denote feature importance below 0.05)

CPU thread count has **high importance** across all predictors
 Many predictors are vendor-agnostic: generalize purely on specification numbers
